| Objectives   | <ul> <li>Understand denitrification as an anaerobic respiration process and the bacteria capable of doing it.</li> <li>Practical work: Study and test a given bacterium or an environmental sample for dissimilatory nitrate reduction: <ol> <li>Nitrate reduction to nitrite</li> <li>Nitrite reduction to N<sub>2</sub>O and N<sub>2</sub></li> </ol> </li> </ul>   |  |  |  |  |  |
| Background   | <ul> <li>In addition to their assimilatory uptake by plants and microbes, inorganic nitrogen compounds can serve as electron acceptors under anoxic or oxygen-depleted conditions during dissimilation. Nitrate or nitrite is used as an alternative oxidant at the expense of an organic or inorganic electron acceptor in anaerobic respiration. They are eventually converted to NO, N<sub>2</sub>O and N<sub>2</sub>. This process is called denitrification (Fig. 1). It is characterized as follows:</li> <li>The products of dissimilatory denitrification are excreted into the environment.</li> <li>The most important enzyme involved in this process is the nitrate reductase which is membrane-bound.</li> <li>Energy is generated via electron transport processes in the bacterial membrane.</li> <li><i>Pseudomonas</i> species, for example, are well-known nitrate reducers.</li> <li>Bacterial species may be differentiated on the basis of their ability to reduce nitrate to nitrite or to nitrogenous gases.</li> <li>In medical microbiology, the denitrification test is diagnostic for the identification of enteric bacteria.</li> </ul> |  |  |  |  |  |
|              | Padax state   |  |  |  |  |  |

|              | ·III NO2 Nitrite  |  |  |  |  |  |
|              | NO Nitric oxide   |  |  |  |  |  |
|              | 0 N2 Nitrogen gas   |  |  |  |  |  |
|              | $NO_3^- + 2e^- + 2H^+ \rightarrow NO_2^- + H_2O \qquad pH\uparrow$  |  |  |  |  |  |
|              | $2 \operatorname{NO}_2^- + 6 e^- + 8 \operatorname{H}^+ \rightarrow \operatorname{N}_2^- + 4 \operatorname{H}_2^- O \qquad p \operatorname{H}^{\uparrow}$   |  |  |  |  |  |
|              | N <sub>2</sub> O acts as a greenhouse gas. In the stratosphere it is converted to NO which contributes to the destruction of the ozon layer. For the environmental impact of denitrification see <u>http://www.epa.gov/globalwarming</u>  |  |  |  |  |  |

|   |  |  |  |

## NITRITE TEST PROCEDURE

The microorganism's ability to reduce nitrate to nitrite is determined by the addition of the diazotizing and the coupling reagent to the test tube

- 1. Label 4 assay tubes (# 1to 4) and add 4 ml distilled  $H_2O$  to each
- 2. Add 20 µl aliquotes from each culture to the appropriate assay tube
- 3. Add 2 ml nitrite test solution to each assay tube
- 4. Allow the color to develop for 15 min
- 5. The intensity of the purple-red color is measured as absorbance at 540 nm in a photometer
- 6. Compare with an appropriate standard calibration

**Results**: In case of a **positive reaction**, you will immediately observe a purplered color in the test tube; i.e. the bacteria are positive for nitrate reduction and produced nitrite. The positive reaction can be written as follows:

Source: http://www.uni-bayreuth.de/departments/ddchemie/wurst/abb9.gif.

In case of an apparently **negative reaction** (no nitrite detected, i.e., the suspension is colorless after the addition of the Nitrite test reagent), further testing must be done.

IS THERE STILL NITRATE PRESENT IN THE CULTURE MEDIUM?

## Addition of zinc powder: chemical reduction of nitrate to nitrite

- 1. Add a small amount ("sharp knife point": ca. 5 mg) of zinc dust to the test tube that tested negative for nitrite production (nitrite test reagent is present in the tube).
- 2. Shake the tube vigorously and allow it to stand at room temperature for 10-15 min.

**Result:** 

- If the medium remains colorless, the test result for nitrate reduction is **positive** (i.e. bacterial nitrate reduction to gaseous compounds took place; nitrate was used up and transformed with no nitrate or nitrite remaining).
- If the medium turns red after the addition of Zn powder, the test result for nitrate reduction is **negative**; nitrate was not used by the microorganisms. It was chemically reduced to nitrite by the test reagent.

|                                   | Observe the inverted Durham tubes for gas production.<br>http://www.cat.cc.md.us/~gkaiser/labmanua/lab8/prgas.html  |  |                            |                        |                            |                                  |  |
| Laboratory Rules &<br>Precautions | <ul> <li>α-Naphthylamine is a carcinogen. On the basis of structural similarity, N-(1-Naphthyl)ethylenediamine might also be dangerous. That's why all precautions pertinent to carcinogens should be observed for this compound. Do not use a mouth-drawn pipet. Wear gloves. Dispose of waste properly (ask assistant).</li> <li>HCl is corrosive. Contact with skin may cause blisters and burns. In case of contact, flush immediately with plenty of water (for at least 15 min.)</li> </ul> |  |                            |                        |                            |                                  |  |
| Goals &<br>Experiences gained     | <b>Microbial analyses:</b><br>The nitrate reduction test is based on the detection of nitrite and its ability to form a red compound when it reacts with sulfanilic acid to form a complex (nitrite-sulfanilic acid) which then reacts with alpha-naphthylamine to give a red azo dye; gases are trapped in the inverted Durham tube.   |  |                            |                        |                            |                                  |  |

| Questions to be answered | 1. | What do the gas bubbles in the Durham tube tell you? Why is gas<br>production without gas analysis not sufficient to claim that denitrification<br>took place ?   |
|--------------------------|----|---|
|                          | 2. | How can you avoid growing fermenting bacteria in an enrichment culture for denitrifiers ?   |
|                          | 3. | Answer the questions:<br>http://www.smccd.net/accounts/case/biol240/NO.html   |
|                          | 4. | For problems see: Section Problems & Solutions under<br>http://www.cdc.gov/ncidod/dastlr/gcdir/NeIdent/Nitrate.html   |
|                          | 5. | How could you make the nitrate reduction test a quantitative one?   |
|                          | 6. | Formulate incomplete denitrification to $N_2O$ and NO as stoichiometrically balanced equations; use methanol as the electron donor.   |
|                          | 7. | Name a few bacteria which are denitrifyers. Does your list contain any obligate denitrifyers or are they all facultative ones ?   |
|                          | 8. | Analogously, sulfate can act as an alternative electron acceptor for certain<br>anaerobes. Name a few sulfate reducers and formulate a sulfate-reducing<br>redox reaction with an appropriate electron donor substrate. |
